LMSC-803324-2

DEFINITIONS

Reliability may be defined as the probability of success in a trial having only two possible outcomes -- success or failure (attributes data). This probability (p) is estimated by the ratio of the number of successes to the number of tests.

The confidence level γ assigned to a statement about some particular statistic assigns a probability to the statement about that statistic. The statement will be true with probability at least γ .

The lower γ confidence limit on the parameter p is a particular value having the property that it is less than or equal to the parameter p with probability at least γ .

The upper γ confidence limit on the parameter p is a particular value having the property that it is greater than or equal to the parameter p with probability at least γ .

Note:

Revision 1 of this handbook was a reprinting of the original issue. Revision 2, this issue, is an expanded reprinting of Revision 1.

LMSC-803324-2

INSTRUCTIONS

The following tables may be used to determine upper and lower confidence limits on the estimate of reliability. They are for attributes data, i.e., when each test conducted is judged either a success or a failure.

To find such a confidence limit, determine the confidence level and the type of limit (upper or lower) desired. Select the proper table. Find the sample size (total number of tests conducted) in the left hand column, and the number of failures observed in the top row. The required value lies in the body of the table at the intersection of the row and column determined by these two headings.

If the number of tests lies between two tabulated values, linear interpolation may be used. If the number of tests conducted is larger than the values tabulated, an approximation to the lower limit may be found in the Poisson table, page 173. The lines which appear on the lower limit charts indicate the number of significant digits to which the Poisson approximation will be accurate.

POISSON TABLE INSTRUCTIONS

The Poisson table provides an approximation to the values found in the previous binomial tables. The approximated value is always less than the binomial value, and is very close to that value when the number of tests conducted is large and the number of failures is small. The levels indicated on each binomial table show the number of digits which can be correctly determined by the Poisson approximation in that region. Above level 2 the binomial value minus the approximated value is greater than 0.0050; within level 2 the error is between 0.0050 and 0.00050; within level 3 the error is between 0.000500 and 0.00005; and below level 4 the error is less than 0.00005.

To determine the approximation to the lower limit of reliability, R_L , find the number of failures observed in the left hand column of the Poisson table and the desired confidence level along the top row. The number in the table which lies at the intersection of the row and column determined by these headings is np . R_L is then obtained by dividing np by the number of tests and subtracting this answer from 1. For example, if 1000 tests were conducted and 3 failures observed, $np = 5.915$ at the 50.0 percent confidence level. Therefore, $p = 0.005915$ and $R_L = 1 - p = 0.994085$.

LMSC-803324-2
MATHEMATICAL METHODS

The tables of confidence limits on pages 4 through 171 were computed from the cumulative binomial probability distribution. The equations for upper and lower limits are as follows:

\hat{p}_U is the solution of the functional relationship defined by

$$P(\hat{p}_U) = \sum_{j=0}^s \binom{n}{j} \hat{p}_U^j (1 - \hat{p}_U)^{n-j} = \alpha \quad \text{if } s < n$$

$$\hat{p}_U = 1 \quad \text{if } s = n$$

$$\hat{p}_L = 1 - \hat{p}_U \quad \text{where } \hat{p}_U \text{ is the solution of}$$

$$P(\hat{p}_U) = \sum_{j=0}^r \binom{n}{j} \hat{p}_U^j (1 - \hat{p}_U)^{n-j} = \alpha \quad \text{if } r < n$$

$$\hat{p}_L = 0 \quad \text{if } r = n$$

\hat{p}_U = upper confidence limit on the probability of success
(i.e., upper confidence limit of reliability)

\hat{p}_L = lower confidence limit of reliability

\hat{q}_U = upper confidence limit on the probability of failure

n = number of tests conducted

s = number of successes observed

r = number of failures observed

α = one minus the confidence level

Newton's method for approximating roots was used to find \hat{p}_U and \hat{p}_L in the above equations, when $0 < s < n$. To find \hat{p}_U , the initial estimation, \hat{p}_{U_0} , was $\frac{s}{n-1}$. For each subsequent approximation:

$$\hat{p}_{U_i} = \hat{p}_{U_{i-1}} - \frac{f'(\hat{p}_{U_{i-1}})}{f''(\hat{p}_{U_{i-1}})} = \hat{p}_{U_{i-1}} + \frac{\sum_{j=0}^s \binom{s}{j} \hat{p}_{U_{i-1}}^j (1 - \hat{p}_{U_{i-1}})^{n-j} - a}{(n-s) \binom{n}{s} \hat{p}_{U_{i-1}}^s (1 - \hat{p}_{U_{i-1}})^{n-s-1}}$$

When $(\hat{p}_{U_i} - \hat{p}_{U_{i-1}}) < 0.000001$, \hat{p}_{U_i} was taken as the value of the upper confidence limit. \hat{p}_L was computed in a similar way (using r in place of s).

The value of \hat{p}_U and \hat{p}_L may also be computed from the β distribution.

$$\hat{p}_L = \frac{s}{s + (r + 1) \beta_{1-a, 2(r+1), 2s}} \quad \text{if } r < n$$

$$\hat{p}_L = 0 \quad \text{if } r = n$$

$$\hat{p}_U = 1 - \frac{r}{r + (s + 1) \beta_{1-a, 2(s+1), 2r}} \quad \text{if } s < n$$

$$\hat{p}_U = 1 \quad \text{if } s = n$$

where

n = number of tests conducted

r = number of failures observed

s = number of successes observed

$$\beta_{\alpha, \nu_1, \nu_2} = \left\{ \beta_{\alpha, \nu_1, \nu_2} \leq \beta_{1-\alpha, \nu_1, \nu_2} \right\} = 1 - \alpha$$

The values in the Poisson table, page 173, were computed from the equation

$$P(\lambda) = \sum_{j=0}^{\infty} \frac{\lambda^j e^{-\lambda}}{j!} = 1$$

where

λ = number of failures observed

e = one minus confidence level

$\lambda = np$ = value in the Poisson table

The values of λ were computed using Newton's method of approximation as before.
